

1. Which are the different ways of configuring a java class as a spring bean?

1. In pure xml approach

bean-config.xml

<bean id , class..../>

OR

2. Spring boot : no xml approach

bean-config.xml --> replaced by Java configuration class (@Configuration)

<bean id , class..../> : @Component | @Service | @Controller...

It's possible to use these stereotype anno --while developing your own spring beans

OR

3.

For the 3rd party classes (eg : ModelMapper , PasswordEncoder...) to be configured as spring bean :

Use @Bean as method level annotation , that can be added under spring config class

eg -

@Bean

public ModelMapper modelMapper()

{

ModelMapper mapper=new ModelMapper();

configure ModelMapper - set matching policy as STRICT => in case of matching names transfer the values from src object to destination n do not transfer null values of the property from src to destination.

return mapper;

}

2. In a Spring boot application ,

What are the defaults ?

The package under which a main class is created is by default the base-package

(This is the name that you specify while creating the spring starter project)

This application class is auto annotated with :

@SpringBootApplication

It's a composed annotation.

It implies that it's a configuration class that declares one or more @Bean methods and also triggers auto-configuration and component scanning.
